

hallmark feature of type 2 diabetes mellitus (T2DM) is the accumulation of islet amyloid polypeptide fibrils in pancreatic islets. Such accumulations form amyloid plaques, referred to as islet amyloidosis. Amyloidosis due to aggregation of amyloid- β is key pathogenic event in AD, whereas aggregation of mature islet amyloid polypeptide (IAPP₃₇) in human islet leads to β -cell dysfunction. Researchers at NIA used a bioinformatic approach to identify two novel islet amyloid polypeptide isoforms: IAPP β , encoding an elongated propeptide and non-aggregating IAPP γ , which is processed to mature IAPP₂₅ instead of IAPP₃₇. They developed a quantitative selective reaction monitoring (SRM) proteomic assay to measure the isoform peptide levels in human clinical plasma and CSF from individuals with early AD and found that their levels were significantly reduced. Further, mature IAPP₂₅ derived from IAPP γ isoform inhibits fibrillation of IAPP and amyloid- β efficiently *in vitro*.

Potential Commercial Applications: The novel IAPP β and IAPP γ isoforms are potential peptidyl therapeutics to counteract with amyloid forming IAPP and amyloid- β in treatments of diabetes and Alzheimer's disease and serve as blood-based biomarkers for Alzheimer's disease.

Competitive Advantages:

- Peptide based anti-amyloid medicine.
- Potential market applications for neurodegenerative diseases.

Development Stage: Pre-clinical (*in vivo* validation).
